IRONHACK · PROJECT 3 · DEMO DAY

AI Use Case Identifier

Company name and website in. A pre-meeting brief with three grounded AI use cases out.

Fritz Tschoepke · autonomous research agent built on LangGraph

PROBLEM AND USER

The first meeting is spent guessing

SMEs ask ”where could AI help us?”

Better be prepared.

THE USER

An AI consultant preparing a first conversation with an SME of 20 to 500 people.

THE PAIN

Either hours of research per prospect, or a pitch that could be for anyone.

WHY IT MATTERS

That meeting decides whether I can convince the client to hire me as a consultant.

AUTONOMY

One trigger, five nodes.

```
python -m app.run --company "Uhlmann Beton" --url "https://uhlmann-beton.de/"
```

site

Homepage, about, careers, job postings

search

News and register entries via Tavily

model

Business model, unit economics, process map

match

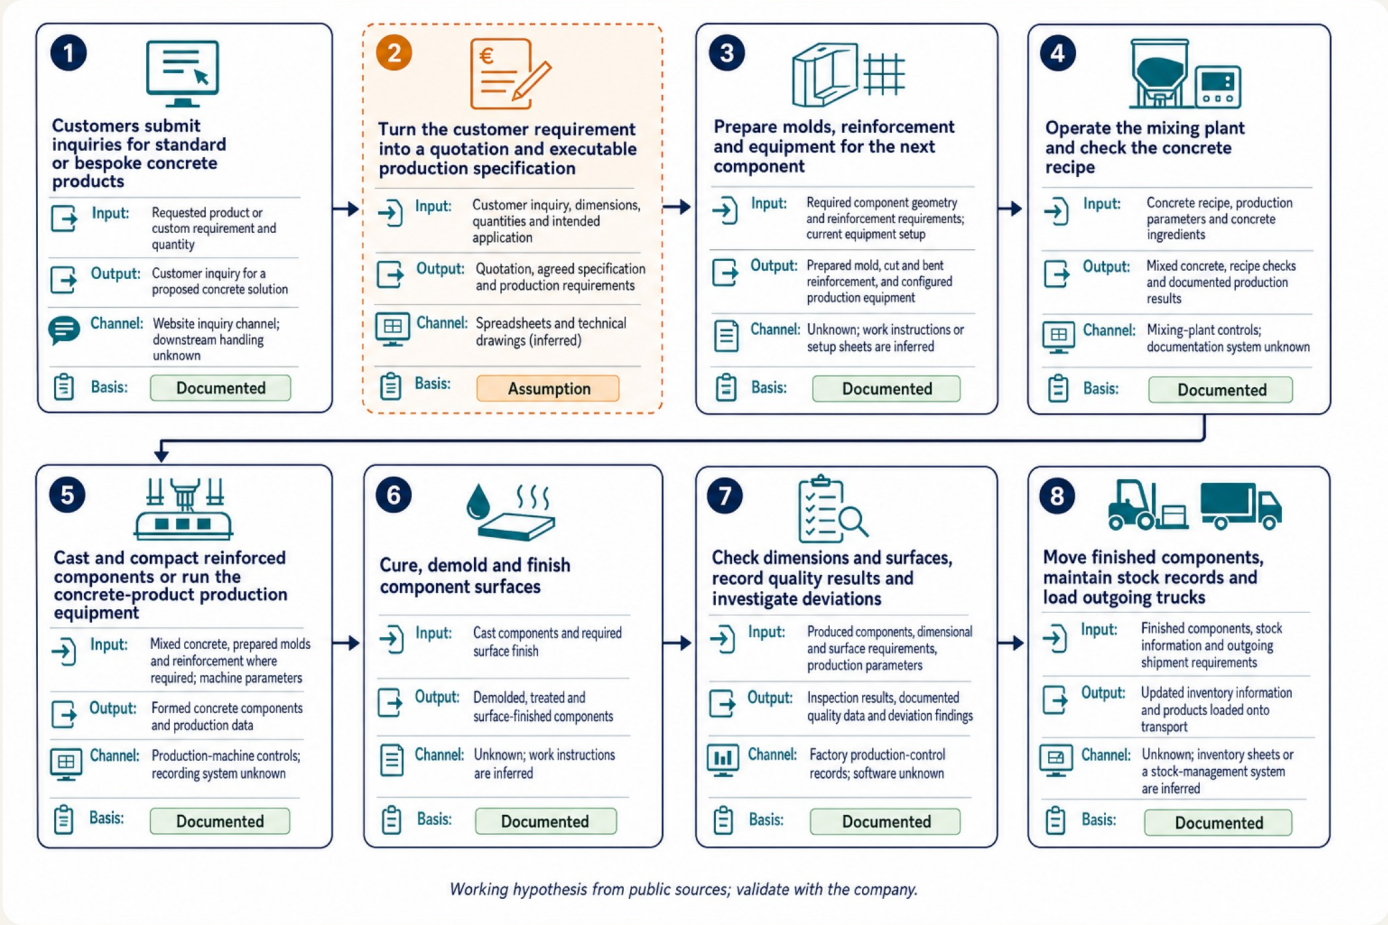

Rubric rating, Pinecone retrieval, rerank, three picks

report

Markdown brief, state.json, process-map image

No node can stop the run. A blocked site or failed call becomes a note, and the note becomes a question for the meeting.

How the company runs, with evidence marked

Working hypothesis from public sources; validate with the company.

DOCUMENTED · 7 OF 8 STEPS

Every claim cites a source id. Python swaps the id for its URL.

ASSUMPTION · STEP 2, QUOTATION

No valid source id? Code downgrades the claim, whatever the model said.

Uhlmann Beton, precast-concrete manufacturer in Rudolstadt. Saved run of 13 November.

THE REPORT · PART 2

Three use cases, plus a more speculative one.

01 · Quick win

Prepare structured inquiry packets for sales

Lever: lower cost per unit
AI runs it

02 · Strategic bet

Assist estimators with geometric quantities for bespoke offers

Lever: more units sold
A person leads, AI assists

03 · Quick win

Refresh an internal finished-stock exception report

Lever: lower cost per unit
AI runs it

OPTION B · AUGMENT, NOT SUBSTITUTE

Engineer-led alternative design service

Speculative, for the meeting

Today Uhlmann prices the design a customer submits. With AI, engineers could offer several costed, manufacturable alternatives early and discuss the trade-offs with the customer.

STACK RATIONALE

Why LangGraph and not n8n

Most of the work is checking what the AI returns. That is easy in code and awkward in drag-and-drop.

EVERY CLAIM IS TRACEABLE

All five steps fill in one shared record. It is saved with every report, so I can see where each statement came from.

THE CODE CHECKS THE AI

A claim without a source becomes an assumption. Use cases must come from the library. If not, the model has to try again.

ONE REPO, ONE COMMAND

Anyone can run it: install, add the API keys, one command. Every change to prompts and rules is tracked in Git.

WHAT N8N DOES BETTER

Connecting apps like web forms, email and CRM, without code.

That is sprint 3. n8n becomes the front door, the graph stays the same.

GO-TO-MARKET · TWO-WEEK SPRINTS

Prove it in the room, then sell it, then open it

Sprint 1

Thinking aid in real first meetings

Eight to ten discovery calls prepared with the brief. Log what was right and wrong.

7 of 10 calls confirm or reject a use case · 3 lead to a proposal

Sprint 2

Paid entry offer

Fixed-price half-day „AI use case workshop“ for manufacturers with a dealer network (a lot of nice use cases here). 50 personalized previews will be sent to suitable prospects.

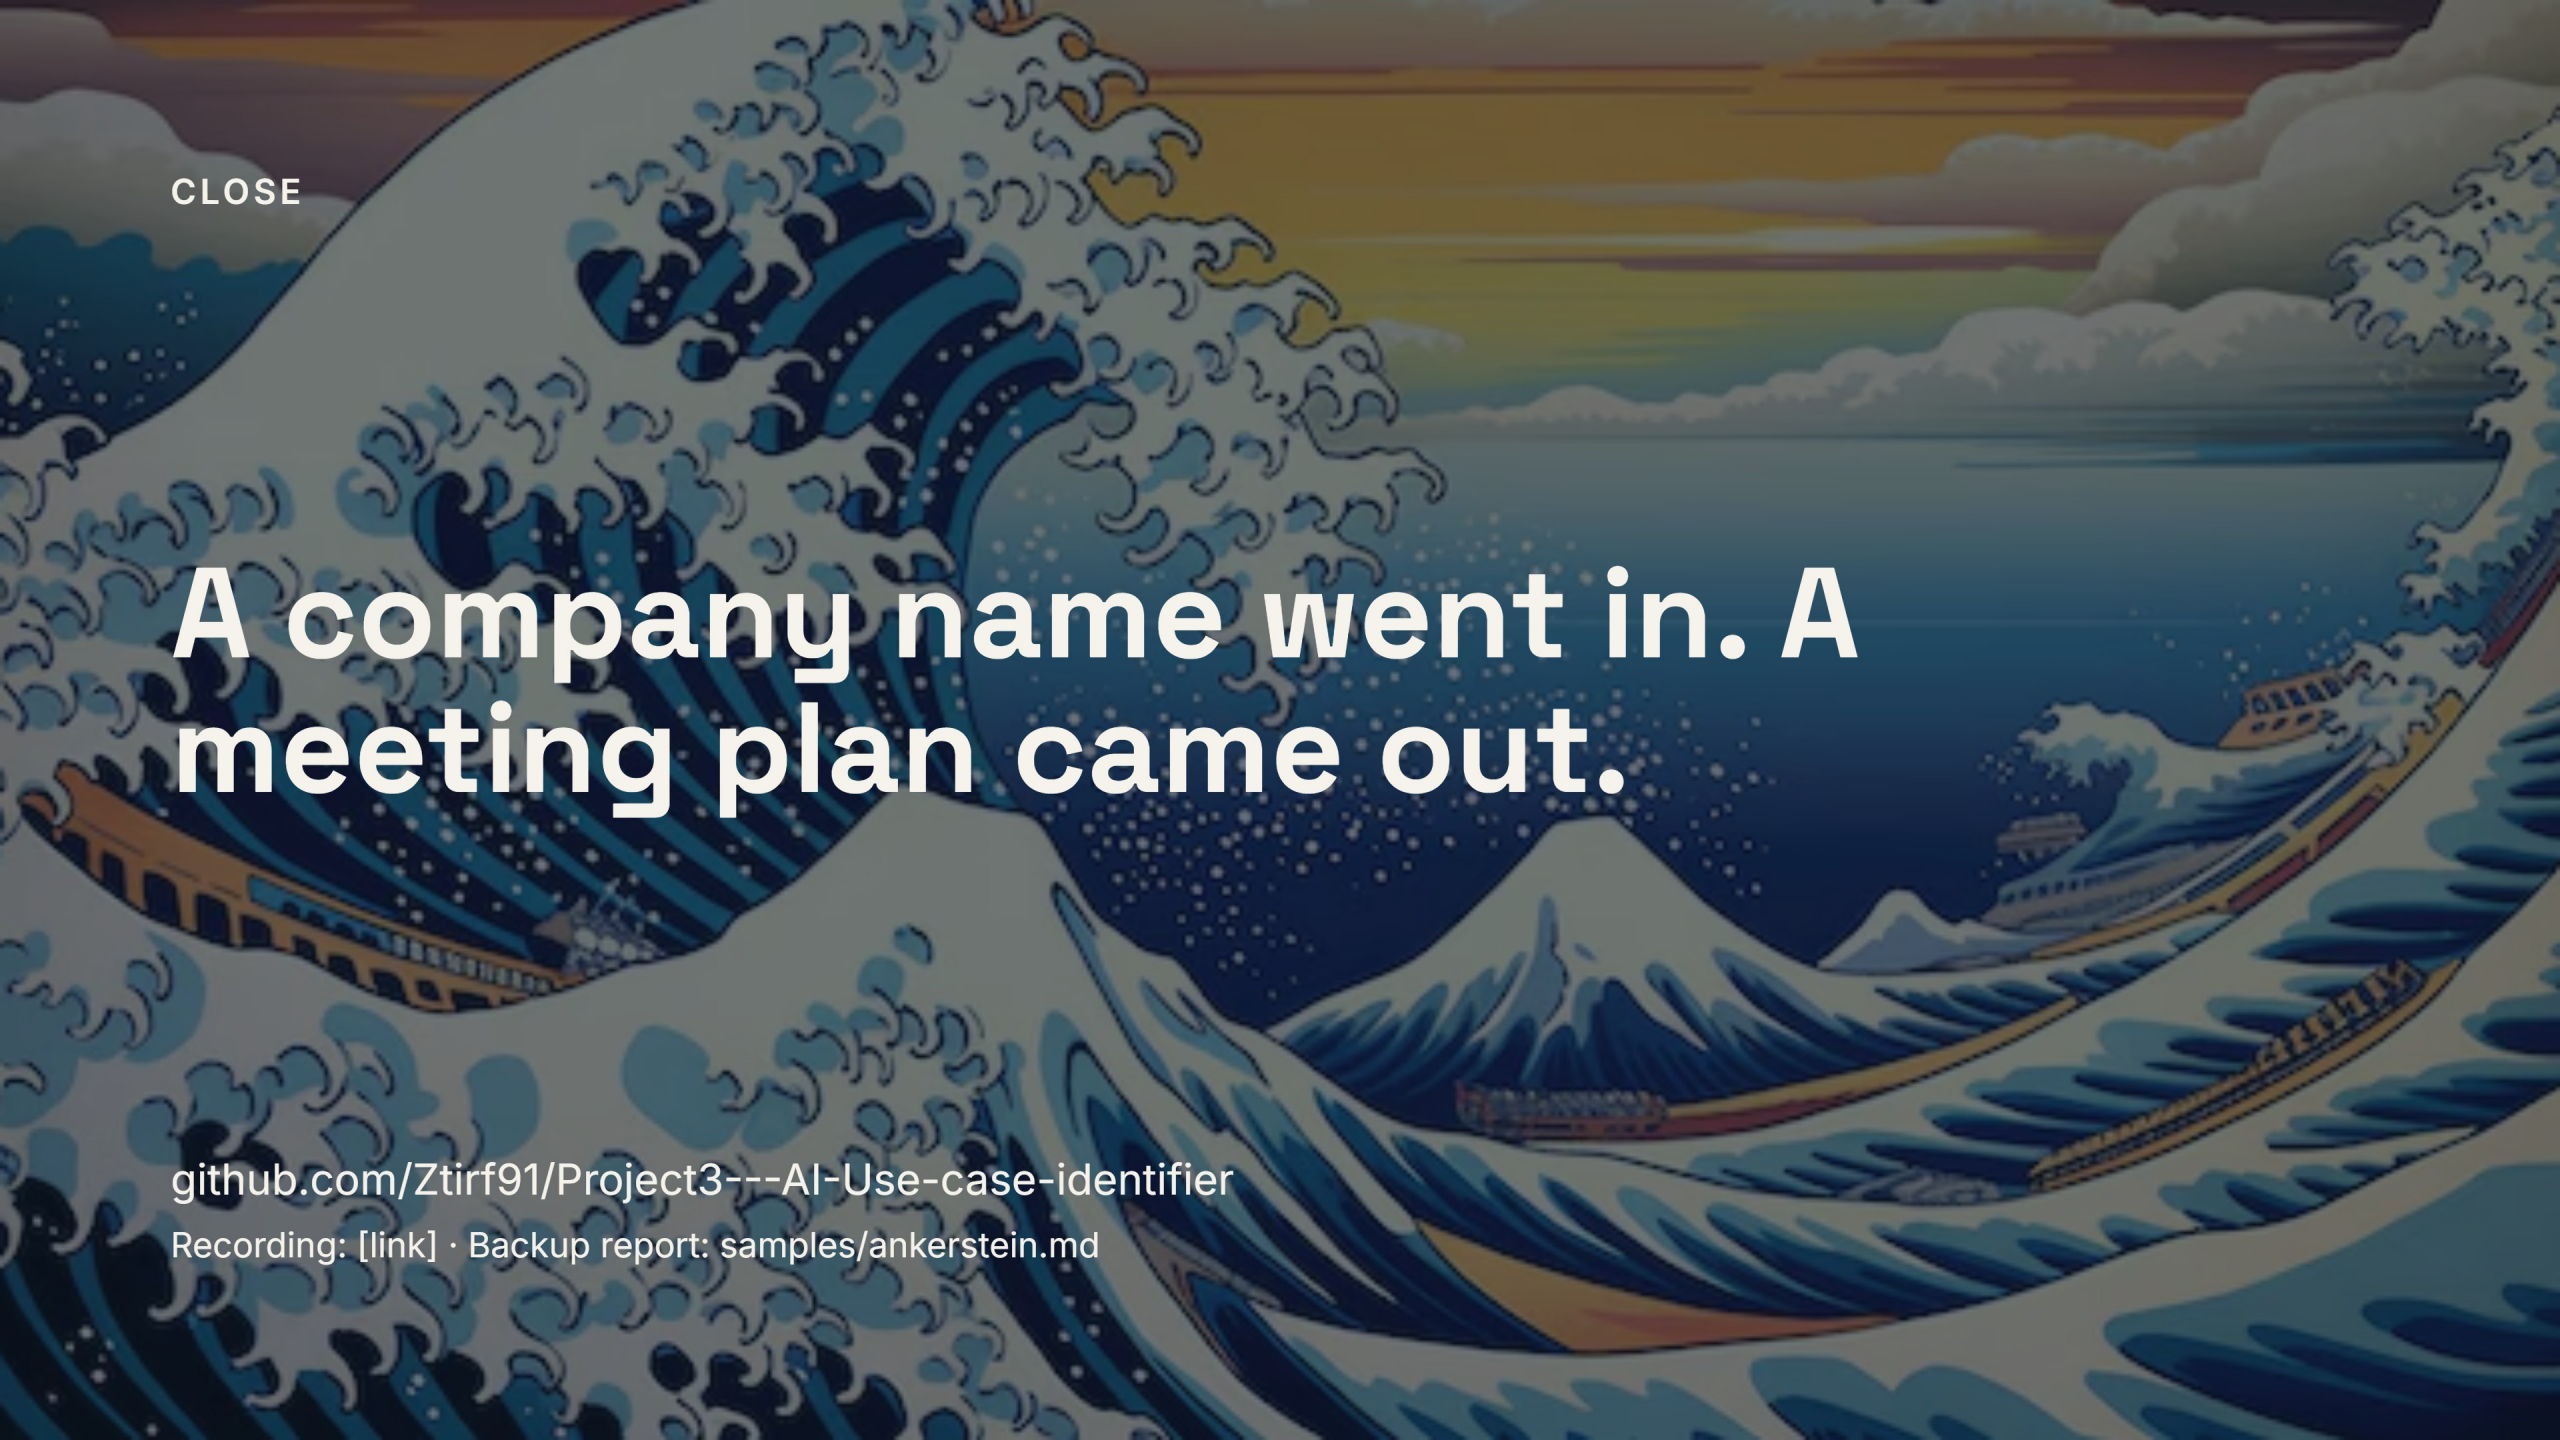

2 paid workshops · 10% reply rate

Sprint 3

Web lead magnet

A form triggers the graph by webhook and returns a light report for email and phone.

25 requests · 20% reachable by phone

CLOSE

A company name went in. A meeting plan came out.
